## STUDY GIST

### Management Science Support for Program/Budget Planning and Prioritization Methodology

#### Principal Findings

1. The greatest potential for the MAMP is the close cooperation it engenders between the AMC materiel developer and the TRADOC combat developer in establishing goals and recommending programs to DA. In many cases, there has been insufficient communication between these parties. The MAMP provides a formal mechanism and a visible product of that communication which is less demanding than the preparation of requirements documents. As a planning tool, the MAMP excels in visualizing program structure and resource requirements for the future.
2. The MAMP software is still under development. The exact informational requirements of MAMP users have not yet been fully ascertained, much less satisfied. The manager is unlikely to know what the best presentation of information is until he sees a sample report. Thus, the work done at BRDEC can be viewed as the development of prototype reports which can be critiqued, improved, and adopted if they are successful.
3. The data contained in the MAMP database requires a lot of work to assemble and maintain. The quality control functions require a significant degree of knowledgeable high level attention.

#### Main Assumptions

1. The BRDEC automated MAMP system can be made to be responsive to BRDEC and CSS/EMW/SOF, independently of software changes that may occur in the AMC MAMP. This specialized software will, however, have to conform with standards set by the AMC system.
2. Any specialized new reports, if they prove to be responsive to informational needs, can become prototypes for additions to the AMC system.

#### Principal Limitations

1. The MAMP software available at BRDEC is generally unavailable elsewhere. This is because of the somewhat technical nature of the computer operating system and the complexity of the software. It will require integration into the AMC MAMP system for non-technical users to receive much benefit.
2. The MAMP program prioritization algorithm is the responsibility of TRADOC. This study analyzed the perceived deficiencies in the current algorithm, but it was felt that the technique could not be unilaterally altered.

A-1 22 20

### Scope of the Effort

This effort was directed toward improving the automated MAMP system in place at BRDEC and applied to the management of the CSS, EMW, and SOF mission areas.

### Objective

The objectives of this effort were to provide management science support to test, analyze, and apply the revised AMC MAMP software; to identify and implement extensions to the MAMP that address BRDEC unique requirements; and to further develop alternative methods to integrate the program prioritization and funding allocation processes.

### Basic Approach

(1) Functional and comparative analyses of the original BRDEC and revised AMC MAMP software were performed to identify all substantive differences in their content and performance. The differences were such that it was determined that the BRDEC MAMP would be made to conform structurally with the AMC MAMP.

(2) Extensions to the MAMP software were added so that the MAMP would be applicable to the BRDEC unique requirements that span across several TRADOC Mission Areas.

(3) Other program prioritization techniques, specifically those that integrate the MAMP into the DA LRRDAP process, were reviewed and implemented to assist in the assessment of reprogramming recommendations.

### Reason for Performing the Study

To provide the necessary support to the Mission Area Manager for the CSS, EMW, and SOF mission areas, in the continued development and production of the Mission Area Materiel Plan.

## FOREWORD

This technical report is submitted to the US Army Belvoir Research, Development and Engineering Center, Fort Belvoir, Virginia by the McLean Research Center, Inc. (MRC), 1483 Chain Bridge Road, Suite 205, McLean, Virginia. This report documents the research performed under Contract Number DAAK70-84-D-0052, Task Order 0016 entitled "Management Science Support for Program/ Budget Planning and Prioritization Methodology". The major portion of the research effort is presented in the four appendices which document the status of the CSS/EMW/SOF MAMP software as of August 1986. They are intended for use as a Reference Manual for system operators.

### INTRODUCTION

#### 1.1 Background

The automated Mission Area Materiel Plan (MAMP) has been under development since December 1984. As a joint AMC/TRADOC program, the MAMP is intended to relate the materiel development initiatives of AMC to the TRADOC developed Battlefield Development Plan (BDP) deficiencies. The objective of the MAMP is to more closely align ongoing and planned Army RDT&E activities with stated Army requirements. The automated MAMP system supports this objective with responsive and comprehensive reports of RDT&E program plans and through consistent application of prioritization techniques to relate the RDT&E to the BDP.

In June 1985, AMC adopted the initial work performed at BRDEC on the automated Combat Service Support (CSS) MAMP and began the process of transforming it to be applicable to all mission areas. AMC provided the first release of its software to the MAMP community in January 1986. At the same time, the mission area assignments were realigned to be consistent with the TRADOC mission areas (when earlier they were based on the DA mission areas in use by AMC). BRDEC was assigned to represent the CG, TROSCOM in his role as Mission Area Manager of the Combat Service Support (CSS), Engineering and Mine Warfare (EMW), and Special Operations Forces (SOF) mission areas.

#### 1.2 Objectives

The objectives of this effort were to provide management science support to test, analyze, and apply the revised AMC MAMP software; to identify and implement extensions to the MAMP that address BRDEC unique requirements; and to further develop alternative methods to integrate the program prioritization and funding allocation processes.

#### 1.3 Technical Approach

These objectives were accomplished through the following efforts:

(1) Functional and comparative analyses of the original BRDEC and revised AMC MAMP software were performed to identify all substantive differences in their content and performance. In many areas, the AMC MAMP system was an improvement over the original BRDEC database. The differences were such that it was determined that the BRDEC MAMP would be made to conform structurally with the AMC MAMP.

(2) Extensions to the MAMP software were added so that the MAMP would be applicable to the BRDEC unique requirements that span across several TRADOC Mission Areas. This involved revising all existing BRDEC MAMP reports to conform to the AMC database structure, and particularly the AMC MAMP control files. All new MAMP reports generated in this effort were designed to generate output appropriate to BRDEC as well as to the designated TRADOC Mission Areas.

(3) Other program prioritization techniques, specifically those that integrate the MAMP into the DA LRRDAP process, were reviewed and implemented to assist in the assessment of reprogramming recommendations.

#### 1.4 Organization of this Report

This technical report presents a complete synopsis of the work that was performed under this Task Order.

Section 2 describes the functional and comparative analyses that were performed and documented in an Interim Report. In addition, it includes the functional analysis of the MAMP database integration process and the text of the recommendation made to AMC to correct inherent defects in that process.

Section 3 documents the techniques used to implement the BRDEC unique reports and the advanced program prioritization algorithms. Examples of these techniques can be observed in the Appendices.

Section 4 presents the findings and recommendations of this study effort. These are focused on the additional actions necessary to continue the development of the MAMP process and to improve its utility to BRDEC.

Appendix A documents the BRDEC MAMP database structure. It contains several unique data files not included in the AMC database.

Appendix B documents the miscellaneous procedures (UNIX shells and C programs) needed to correctly manage the BRDEC MAMP.

Appendix C presents samples of each of the BRDEC MAMP reports, along with instructions for running those reports.

Appendix D provides a record copy of the source code for each of the ACE reports contained in the BRDEC MAMP system.

## Section 2

### FUNCTIONAL AND COMPARATIVE ANALYSES

#### 2.1 Background to the MAMP Database Transition

In early 1986, BRDEC received the first release of the AMC generated MAMP system. This effort was a major restructuring of the MAMP system software from its configuration in 1985. It incorporated many of the features of the RDA database system, and of the earlier "mat\_plan" database and Informix ACE reports used at BRDEC. It added a menu structured user interface to enable users with less computer knowledge to operate the system and data entry forms to reduce the likelihood of data entry errors.

The new MAMP database posed a challenge to the existing CSS/EMW/SOF MAMP system. First, our database needed to be revised from the "mat\_plan" structure to the "mamp" structure imposed by AMC. This would allow the convenient exchange of data among the various MAMP sites. In addition, our existing ACE reports needed to be revised to accommodate the changes to the database structure and data elements.

#### 2.2 Initial Review of the MAMP Database

An initial review of the revised MAMP database led to the MRC Interim Report of May 1, 1986, which is reproduced at Figure 2-1. It reported that the new "mamp" database was an improvement over the old "mat\_plan" database, but that the total system design was still not well thought through. In particular, it pointed out that many of the new system features, like the "perform" data entry screens, were particularly difficult to use and would be unsuitable for our requirements. It was also noted that the new "mamp" database structure would not allow for all the existing and contemplated reports for the CSS/EMW/SOF MAMP.

During the preparation of this report, the CSS/EMW/SOF MAMP database was transitioned in its entirety to be compatible with the AMC MAMP software. This meant that all common data elements between the "mamp" and the "mat\_plan" databases were brought into conformance with the "mamp" database. Any additional data elements not included in the AMC standard "mamp" database were added to "mamp" as separate files so as not to corrupt the standard file definitions. Subsequently, all existing CSS/EMW/SOF reports were revised to utilize that new structure.

## INTERIM REPORT ON THE MAMP DATABASE

Prepared By: Neil Romstedt  
McLean Research Corporation  
1 May 1986

### A. OBJECTIVE

This interim report is provided in accordance with Subtask 1 of Task Order 0016 of DAAK70-84-D-0052. It documents the preliminary findings of this contractor in the use of and transition to the AMC revised mamp database and software.

### B. DATABASE DIFFERENCES

The mamp database is not significantly different from the mat\_plan database. Both contain approximately the same data about systems, workpackages, and deficiencies. The major difference between the two is the organization of funding data for workpackages, tasks, and projects. While mat\_plan uses a single record to include the funding stream over the eight year horizon of the planning data, the mamp uses individual records for each of the years in which funding data is provided. The mamp technique reflects the database structure used in the RDA budget database, from which the data is derived. This technique has advantages and disadvantages. The primary advantage is that if funding for any particular year is blank, then the record does not have to be entered in the database. In the mat\_plan database, the field is reserved and set to 0.0 if no data is entered. The primary disadvantage is that multiple records must be used for any one workpackage, task, or project. Each record has overhead in terms of the repeated information needed to identify and link the record to the other associated data. In general terms, if the overhead can be kept small, then it is usually preferred to have separate records. However, the complexity of the data in the MAMP dictates that there be a large quantity of overhead data.

For example, to correctly link a specific funded, unfunded, and guidance quantity for a workpackage for one year, the mamp database requires the workpackage command, category, subcategory, pe, project, task, workpackage number, and year. These data total 50 bytes per record (out of about 80 total bytes). In addition, the index overhead of about 35 bytes per record must be included. If four years of data were entered, then the four records would consume a total of about 460 bytes. If the data were organized as a single record of eight years, then the overhead would be 44 data bytes per record (out of about 290 bytes total) and the index overhead would be about 20 bytes, for a total of 310 bytes. Some of this disparity could be eliminated through better database design practices to eliminate unnecessary overhead data, and this action should certainly be taken. The potential future expansion to an Extended Planning Annex (EPA) forecast of an additional 8 years (16 years total) of RDT&E funding could clearly alter the balance in the favor of individual records, so this issue should be carefully considered.

In addition, the organization of the data into individual years presents some intriguing and challenging problems to the casual ACE report writer. The level of complexity of the report writing problem multiplies by the number

Figure 2-1. Interim Report on the MAMP Database

of individual data records which must be handled. Without clever programmers and thorough training, the reports quickly become so complex and the files produced so large that the user is deterred by energy and time from using the database to solve his unique problems.

Both the mamp and mat\_plan databases suffer from being not well thought out and designed. The mamp database deserves our attention since it is the database that AMC has designated and will use. There are several design improvements that could be suggested at this point, but since a thorough redesign is appropriate no recommendation is made at this point. Some issues to consider in the redesign are:

(1) What is sufficient and unique to identify a workpackage? Does the identity chain include command, category, subcategory, pe, project, task, and workpackage number? Or is the command, category, and workpackage number sufficient? I believe that the command, pe, project, task, and workpackage number are enough, and that the category and subcategory of any particular project should be maintained in the project file.

(2) What does the acquisition code have to do with the linking of systems to deficiencies and why is it in the ssndef file?

(3) Why is the priority of a particular pdip contained in the lrrdp file? This allows careless data entry clerks to put different priorities in for the same pdip/increment. The pdip priority, along with any other vital data about the pdip that may be required should be in a pdip file.

(4) Workpackage contribution values to systems that they are linked to need to be included in the wkpsys file. This change is critical, and has already been done (unilaterally) for our mamp database.

(5) The project index field in the project control file needs to be switched to allow duplicate entries for any one project. This will allow one project to be used against different mission areas, commands, or flags. Currently the schema will allow only one entry for any one project. This same problem is present in the workpackage control file. Both have been changed (unilaterally) for our mamp database.

(6) The system title should be in the ssn file and not the lrrdp file since it is the same for each pdip/increment that a system may be linked to. This change will make the ssn file, not the lrrdp file the key file entry point for systems.

(7) Why can't the workpackage funding data and the workpackage statement data be combined into a single file? Both use exactly the same structure for identifying the relevant workpackage and year concerned. Combining them will eliminate half the overhead of the two files. This might conflict with a decision to merge the funding data into a single record.

(8) What purpose is the workpackage control file that is not served by the project control file?

(9) The workpackage description file could be merged into the wkpkg file. This would create a long workpackage record but would cut the overhead by half.

Figure 2-1. Interim Report on the MAMP Database (Continued)

(10) The classification identification procedures that we use in the mamp are not very thorough. It is difficult to tell, except for the text descriptions, what of the data presented in any of our reports is SECRET or CONFIDENTIAL. The data fields used in the data base to tell us the classification of the data are ambiguous as to which data is to be marked. We need to rethink this process and set some specific standards that we will follow.

#### C. PERFORM SCREENS

The concept of using perform screens to simplify the operator interface for data entry and application is well understood. In general, the average computer user cannot be trusted to correctly type in data and is usually not well enough versed in a computer's operating system to execute programs without simple and straightforward instructions. The perform screen is intended to provide a common user interface, which with some brief training will allow the data entry clerk and the database administrator alike to access and use the database. This cannot completely correct for erroneous data but using a systematic system like the perform screens can catch a significant fraction of the mistakes that might and probably would occur if the data were entered directly into the database (using enter2).

The perform screens exact a performance degradation on data entry. In well designed screens this penalty will be negligible. However, in the screens provided by AMC, the penalty is terrible. It takes about four times as long to enter data using the perform screens as compared to enter2. Then as an extra little kicker, to exit the perform screens and correctly update the data base, the AMC software forces the user to execute some hidden processes that check to see that all the software defined codes are correct. This process takes about 30 minutes and completely ties up the user's terminal. Furthermore, it also completely ties up the database so that other users cannot gain access to the database to enter their own data. From our experience, the use of the existing perform screens is a huge waste of time. Although it may be appropriate for an occasional user, it is not appropriate for the massive data entry and short-fuzed reporting requirements that the MAM faces.

The perform screens should be used with caution until they can be fixed. This fix should be prepared along with the database redesign discussed earlier.

#### D. AMC PROVIDED REPORTS

The AMC provided reports are a reasonable, but incomplete, clones of the reports that were being used at Belvoir in the summer of 1985. Since that time the Belvoir reports have changed significantly in content and quantity. The AMC System Summary, Deficiency Summary, and Commodity Summary are adequate but slightly confusing. The use of the control codes and control names to access the desired systems, deficiencies, and commands is not well documented and not intuitive. We were initially unable to reliably get reports out of the AMC system - probably because we did not understand it. The AMC software appeared to produce unpredictable results, like not producing a System Summary for all systems owned by Belvoir when the report is asked for using the menu structure. Obviously, either the wrong questions were asked or the wrong answers provided. This will become very frustrating for other users who have no recourse to run their own reports.

The AMC reports are a little faster than our own. I would guess about

Figure 2-1. Interim Report on the MAMP Database (Continued)

20 percent faster. But these reports also tie up a user's terminal so that no other work can be done while the reports are being run. Typically the user will select output to the printer, since most people need printed reports, but if the printer breaks down during the print job (a frequent occurrence here) then the user is forced to rerun the whole report. The AMC reports appear to have no capability to set the starting page for any one report. Thus, we could not get the reports automatically page sequenced for our MAMP volumes.

Fortunately, we do not have to rely on the performance of those reports. Our own ACE reports are completely within our control to modify and use. We should continue to use and develop them as our needs change. We should offer those reports to ALMSA and other MAMs for their consideration.

#### E. CHANGEOVER TO THE MAMP DATABASE

The changeover in data from the mat\_plan to the mamp database has been completed. The process of moving the data took approximately 16 hours, but much work in scrubbing the data that is there remains. In moving the mat\_plan data, some of it was corrupted by the AMC provided integrated database. This problem is discussed in detail in paragraph F below.

The changeover in reports to the mamp database is proceeding more slowly. I have moved 8 old reports and created 5 new ones in the last week. There is still lots more to do in this regard. The changeover requires preparing some temporary database files, going through the programs and changing the variable names, adding the control code as well as the control name, and rechecking all the linking between files to ensure that it is being done properly. I estimate that the reports will all be transferred within the next three weeks. The priority will be given to the reports that constitute the MAMP document.

#### F. DATA FLOW AND TRANSFER

The data flow process for the integrated MAMP is not well thought through. There is the significant likelihood that there will be circular data flow, so that bad data propagates throughout the system and that errors cannot be reliably corrected. This will occur if the AMC data integration process can not distinguish between scrubbed data from a MAMP or RDA site and data that was not checked by a MAMP or RDA site because it was not relevant to that data manager. Thus, our data errors will be picked up by all other MAMs, and returned to us at some later date in the circular flow, after we have hopefully found and corrected those errors in our own database.

One solution to this problem that we can implement at Belvoir is to maintain a physically separate "integrated" database on our Plexus. There will be room for this when the mat\_plan is retired to tape. Then, we will read the AMC tapes into this other database, and carefully control the transfer of data from the integrated database into our mamp database. All of our corrections and data submissions will come from our mamp database to ensure that we are not contributing to the circular data flow.

This approach will also allow us to remove from our mamp database any data that is obviously not appropriate to our mission. If we can get rid of the data that we do not use, then our reports will run faster and our submissions to AMC will not include some other MAMs bad data.

We should also carefully consider the impact of unilateral database changes

Figure 2-1. Interim Report on the MAMP Database (Continued)

on our capability to feed the AMC data submissions. At this point, the two changes we have made will require some special attention in preparing the tape. These changes were critical so they were made, but the decision to make additional changes will magnify the compatibility problems we will likely face.

#### G. NEW INFORMIX RELEASES

Relational Database Systems has released several new products with the Informix system. The basic Informix package now includes SQL, their version of the IBM structured query language. They have an advanced report writer called 4GL for 4th generation language that they sell as an option.

Another intriguing option is the optional C programming tools package that they sell (Informix-ESQL). These tools consist of a subroutine library that any C program can call to access the database and index files. It appears that any competent programmer can directly access the Informix database from a C program to produce reports (or whatever) without having to write special drivers or use the proprietary ones developed by IITRI.

#### G. CONCLUSIONS

We are now using the AMC mamp database as best we can. The process of moving our established reports is underway. Uninterrupted attention is required to ensure the success of this venture between now and June.

### 2.3 Subsequent Modifications

Since its initial release, the AMC MAMP system has undergone four revisions. Each revision has added new database fields and/or files, new or modified reports, and appropriate menu entries and data entry forms to support its enhanced capabilities. To its great credit, the AMC installation instructions have been very thorough and the system has worked exactly as advertised with each revision.

The installation of each revision takes approximately four to eight hours of computer time. The installation process consists of reading in the new release tape, positioning the files in the appropriate directories, and running the installation shell programs. These shell programs automatically update the old database files to their new structure, create new files, add any default data values, revise the menus and perform screens, and recompile and relink the C programs that support the system. During this period the computer is unavailable for other MAMP work. In addition, the changes to the database structure must be carefully examined to determine their impact on the CSS/EMW/SOF MAMP reports. Whatever changes are present must be completely integrated into our database to keep it in conformance with the AMC structure and yet still allow the running of our own reports. This transition imposes an additional workload of approximately four to ten days, depending upon the extent of the required changes to the ACE reports.

### 2.4 Database Integration Process

One of the goals of the MAMP system is the convenient and rapid exchange of data among the MAMP sites and AMC. An "integrated" database is envisioned where data entered in at one site is available to all users. Because there are many different sites, and they use physically separate computers which are not electrically interconnected, the data used at each site is actually quite distinct. Periodically, the data must be collected and joined together into a single, larger database. This process is initiated with a data tape submission from each MAMP and RDA site to AMC. AMC then consolidates the data and returns the integrated database to the MAMP sites to replace the earlier data. Then, at least until the data is changed by the Mission Area Managers, the MAMP sites will all be using the same data.

The problem of circular data flow that is inherent with this technique was described in the Interim Report. In fact, for the integrated database that was distributed in June 1986, approximately one month of productive effort was lost to the CSS/EMW/SOF system because the integrated database required extensive review and corrective action to restore it to its original status. Bad data that was introduced into the MAMP database during the integration process had corrupted the scrubbed data in the CSS/EMW/SOF system. This bad data could only be identified through close examination and comparison with reports produced under the pre-integration database.

This bad experience led to the BRDEC proposal in July that AMC adopt a more controlled procedure for the database integration process. The text of the proposal, with a detailed procedure that might be followed, is presented at Figure 2-2. This proposal was immediately adopted by AMC, and implemented in August throughout the MAMP system. Its actual effectiveness at correcting the circular data flow problem will be determined at the next data submission.

## PROPOSAL FOR MAMP DATABASE INTEGRATION

### A. OBJECTIVE

The objective of this paper is to propose a procedure which will greatly speed the process of MAMP database integration and provide the greatest assurance possible that the integrated database will contain only quality data.

### B. BACKGROUND

One of the problems yet to be faced by the MAMP process is establishing a structured data flow. Responsibilities for data, its accuracy and its completeness have not been assigned to anyone. At present, we appear to be operating on the principle that more data is better, regardless of where it comes from. On the face of it, this principle is flawed. The database should contain only quality data that has been scrubbed and approved by a responsible authority. Otherwise, we are wasting our time in a "garbage in - garbage out" paper production effort.

Each MAM administrator spends most of his time, and most of his staff's time, paying attention to the details of the data he uses for his MAMP. The database is constantly being updated as new information is developed, systems and programs are built, deficiencies and contribution values are assigned, and data presently in the database are scrubbed.

The MAMP database integration, as it occurred in March-April and May-June, aggravates the problem of data quality. In March, we all sent in data tapes to AMC containing the best data we had at that time. Some of that data was incomplete and inaccurate. In April, we received the consolidated data with everyone's best data as of March. Naturally, we continued to focus on and improve the data pertinent to our own MAMPs and we ignored the data that was not pertinent. In May, we sent in another data tape to AMC for integration.

In June, we got back the integrated database but it included all the bad data that we had just spent the last two months cleaning out of our database!

The reason for this is that just as the CSS/EMW/SOF MAM administrator spent no time trying to clean up the FS MAMP data (or anyone else's for that matter), so the FS MAM administrator spent no time on CSS/EMW/SOF data. The result of the integration process is to perpetuate bad data throughout the system. Instead of being identified and eliminated, the bad data looks just like good data and so is redistributed to all MAM sites. This chaotic situation has to be stopped at the time of database integration. The next AMC data call is planned for 21 July and we must be prepared to implement a revised procedure immediately.

Two procedures are proposed to ensure only the best data is integrated into the AMC database. First, only scrubbed data should be sent to AMC by each MAM site. If the MAM administrator is not responsible for that data, then he should not send it in. Second, AMC should not accept data for which the MAM administrator is not responsible and should establish automated means

Figure 2-2. Proposal for MAMP Database Integration

to identify and reject that data.  
C. CONTROL FILES

The correct mechanism for establishing what data the MAM administrator is responsible for is through the control files. Control files are maintained in the MAMP database for Deficiencies (defctl), Systems (ssnctl), Projects (prjctl), and Workpackages (wkpctl). The control files allow the MAMP software to automatically select the specific data out of the database that is pertinent to any one MAMP.

The control file structure is a bit difficult to grasp at first, but it makes sense when you understand that it can be used for a wide variety of control functions and that the same structure is consistently applied in all of the control files.

The control files use the field "code" (dcl\_code, scl\_code, pcl\_code, and wcl\_code) to denote whether the record refers to a TRADOC Mission Area, a DA Mission Area, an MSC, or a Flag. Thus, in the same file, a single system could be designated as being included in a TRADOC mission area (EMW), a DA mission area (CSS), a command (BELVOIR), and a flag (LOG R&D) MAMP. This gives the database the flexibility to be used for other purposes than just the current TRADOC Mission Areas of interest today. If a MAM site cares to have multiple MAMPs in a single database then the control files provide a way to keep them straight. At the moment, our concern and responsibility is only for the TRADOC Mission Areas that have been assigned. They are all designated by using the code = 1.

The control file field "name" (dcl\_name, scl\_name, pcl\_name, and wcl\_name) are used to separate out the Mission Areas, Commands, or Flags, depending upon the value of the "code" field. So at Belvoir, we use "CSS", "EMW", and "SOF" in the "name" field. The field has been set to twelve (12) characters wide to accommodate the maximum size of a command name (should the code = 3), although all the TRADOC Mission Areas are two or three characters wide.

So, if the FS MAM administrator is using data in the database, then his deficiencies, systems, projects, and workpackages are identified by corresponding records in the control files with code = 1 and name = "FS". This is the same criteria that should also be used to automatically select out the data that should be sent to AMC in a data call.

#### D. SPECIFIC FILES TO SEND AND PROPOSED PROCEDURES

The following paragraphs will discuss each file that should be sent, and the criteria that should be used to select the specific records to send.

The Informix command "Informer" should be used to select these records. The UNIX/Informix commands to do this are shown for each file. To get started type:

```
cd                (to get you to the home directory)
cd data           (or wherever you want the output files)
rm -i *           (to get rid of all the old .uld files)
informer mamp
```

Figure 2-2. Proposal for MAMP Database Integration (Continued)

I have used the CSS mission area to illustrate the process. Just substitute your own mission area name in for CSS wherever it is shown.

1. SSNCTL: The System Control File. Systems are selected in conjunction with the combat and materiel developer, appropriate for the mission area.  
  
 unload ascii ssnctl where scl\_code = 1 and scl\_name = "CSS"  
 to "ssnctl.uld";
2. DEFCTL: The Deficiency Control File. Deficiencies are assigned to MAMs.  
  
 unload ascii defctl where dcl\_code = 1 and dcl\_name = "CSS"  
 to "defctl.uld";
3. PRJCTL: The Project Control File. Projects are assigned to MAMs.  
  
 unload ascii prjctl where pcl\_code = 1 and pcl\_name = "CSS"  
 to "prjctl.uld";
4. WKPCTL: The Workpackage Control File. This file is optional. It is used to identify specific workpackages in a mission area when the entire project cannot be identified using the project control file. This would occur if the project were shared among two mission areas.  
  
 unload ascii wkpcctl where wcl\_code = 1 and wcl\_name = "CSS"  
 to "wkpcctl.uld";
5. DEF: The Deficiency Description File. The assigned deficiency manager should be responsible for any updates and corrections to the deficiency data.  
  
 unload ascii def where dcl\_code = 1 and dcl\_name = "CSS"  
 joining def\_def = dcl\_def to "def.uld";
6. SSNDEF: The System to Deficiency Linkage File. The assigned deficiency manager should be responsible for all entries against his deficiencies. The system manager can nominate linkages to deficiencies, and enter unrated linkages into the integrated database, but must coordinate with the deficiency manager to have a contribution value assigned and entered into the database.  
  
 (find linkage for all mission area deficiencies)  
 read into a ssndef where dcl\_code = 1 and dcl\_name = "CSS"  
 joining ssndef\_def = dcl\_def;  
  
 (find linkage for all mission area systems)  
 read into b ssndef where scl\_code = 1 and scl\_name = "CSS"  
 joining ssndef\_ssn = scl\_ssn;  
  
 (find MA systems linked to non-MA deficiencies)

Figure 2-2. Proposal for MAMP Database Integration (Continued)

```

assign c = b minus a;

(blank out the contribution values for these linkages)
read into d c.ssndef_ssn c.ssndef_def cv=" " c.ssndef_acq_code;

(add together the two linkages of interest and unload)
assign e = a union d;
unload ascii e to "ssndef.uld";

```

7. LRRDP: The System to PDIP Linkage File and Procurement Funding Stream. The system manager will enter in new records into the lrrdp file for all systems assigned NSIs and for systems with SSNs that were forgotten in the DA LRRDAP. The funding data for these additional entries will be all zeros. AMC will ensure that the latest LRRDAP funding data and PDIP alignments and priorities are reflected in the integrated data base.

```

unload ascii lrrdp where scl_code = 1 and scl_name = "CSS"
joining lrrdp_ssn = scl_ssn to "lrrdp.uld";

```

8. SSN: The System Description File. The system manager will enter in and correct system description data.

```

unload ascii ssn where scl_code = 1 and scl_name = "CSS"
joining ssn_ssn = scl_ssn to "ssn.uld";

```

9. WKPKG: The Workpackage Definition File. The workpackage manager will enter in or revise the workpackage to PDIP linkage into this file. Workpackages are identified by belonging to controlled projects and/or by being controlled workpackages themselves.

```

(find all workpackages that are part of controlled projects)
read into a wkpkg where pcl_code = 1 and pcl_name = "CSS"
joining wkpkg_proj_idx = pcl_idx;

(find all workpackages that are individually controlled)
read into b wkpkg where wkp_code = 1 and wkp_name = "CSS"
joining wkpkg_no_idx = wcl_idx;

(join the workpackages together and unload)
assign c = a union b;
unload ascii c to "wkpkg.uld";

```

10. WKPSYS: The Workpackage to System Linkage File. The MAM will enter in or revise the linkages and include criticality factors as needed. The system manager will be the sole authority to assign the criticality factors. The project/workpackage manager will nominate linkages for review by the system manager. Note that this file should completely replace the mamp file in the RDA database.

```

(find linkages for all mission area systems)
read into a wkpsys where scl_code = 1 and scl_name = "CSS"
joining wkpsys_ssn = scl_ssn;

```

Figure 2-2. Proposal for MAMP Database Integration (Continued)

```

      (find linkages for all mission area workpackages)
read into b wkpsys
joining wkpsys_wkpkg_idx = c.wkpkg_wkpsys_idx;      (using c above)

      (find all MA workpackages linked to non-MA systems)
assign d = b minus a;

      (blank out the criticality factors for these linkages)
read into e d.wkpsys_idx cf=0;

      (join together the two files of interest and unload)
assign f = a union e;
unload ascii f to "wkpsys.uld";

```

#### E. CONTROL REQUIREMENTS FOR INTEGRATION

AMC should take care to ensure that the principles applied here are followed throughout the integration process. Particular emphasis should be given to the responsibilities for data input from each participant, so that a MAM administrator will contribute only the data for which he is responsible. Even so, AMCs automated database integration mechanisms should not accept data that does not conform to these principles:

1. Deficiency related data comes from the deficiency manager only.
2. System related data comes from the system manager only.
3. RDTE related data comes from the MSC through the RDA database only.
4. Other workpackage data comes from the RDTE project manager only.

There are bound to be conflicts in the data records, even after conforming to these principles. Conflicts in linkage files should be resolved in favor of the deficiency manager and then the system manager. Conflicts in system files should be resolved in favor of the designated TRADOC proponent for that system (as indicated in the `ssn_tradoc_pro` field).

#### F. FUTURE CONSIDERATIONS

AMC should give some consideration to the eventual need for a PDIP control file, since PDIPs are assigned to TRADOC proponents and the direction of our future efforts will be more closely aligned with the PDIP structuring process.

Figure 2-2. Proposal for MAMP Database Integration (Continued)

## Section 3

### EXTENSIONS TO THE CSS/EMW/SOF MAMP

#### 3.1 General

The work required by this Task Order directed the evolving MAMP toward addressing three new areas. First, the existing MAMP reports were modified and the database structures established to allow their application to BRDEC management tasks. Second, the MAMP program prioritization techniques were incorporated into a series of new reports which show the critical fiscal reprogramming decisions which might be made, and what their likely impact would be on the executability of RDT&E programs. Finally, these efforts culminated in a second new series of reports, which depict the consequence of DA LRRDAP priority decisions and which institute the MAMP prioritization of RDT&E programs into the PDIP submission process.

#### 3.2 BRDEC MAMP Reports

In keeping with the revised MAMP database structure, it is now possible to designate command names as the control file filters. The significance of this is that every MAMP report can be produced for BRDEC with no additional programming required. What is needed is an up-to-date and complete list of all systems, projects, workpackages, and deficiencies of interest to BRDEC. This list must be maintained within the database, just as are similar lists for the CSS, EMW, and SOF mission areas. Preliminary BRDEC control file lists were generated in June and these have sufficed without modification to date. However, this data should be reviewed and updated if necessary to ensure that the correct MAMP data is being represented as pertinent to BRDEC.

#### 3.3 MAMP Program Prioritization Technique

##### 3.3.1 The Existing Prioritization Technique

The methodology employed to rank order systems and workpackages in the MAMP has been directed by TRADOC. It computes a score for a system based on the Battlefield Development Plan (BDP) deficiencies it supports and its assigned contribution value to the solution of each of those deficiencies. While the linkage between systems and deficiencies may be proposed by the AMC materiel developer, the contribution values are assigned by the TRADOC mission area representatives. Values from A to E (and X) are assigned. The TRADOC representative is instructed to use no more than one A rating for each deficiency. A geometric progression is used to translate the letter value into a numerical score, as follows:

<u>Letter</u>	<u>Weight</u>
A	16 points
B	8
C	4
D	2
E	1
X	0

The deficiencies themselves are also weighted according to their numerical sequence. This is in keeping with the TRADOC rationale for placing the BDP deficiencies in numerical order. BDP deficiency number 1 is more important than deficiency number 2, and so on. The mathematical representation which describes the relative value of the deficiency is:

$$\text{Deficiency Value} = (500 - \text{Deficiency Number}) / 500$$

This places the deficiency value in the range between 1.0 and 0.0 (so long as the deficiency numbers do not exceed 500). Other formulations have been proposed which have provided a greater relative value to lower deficiency numbers, but these have been shown to have only a marginal impact on the system rank ordering results obtained in actual test samples.

A system score is computed as the product of the deficiency value times the contribution weighting, summed over all deficiencies it supports:

$$\text{System Score} = \sum \text{Contribution Weight} \times \text{Deficiency Value}$$

The higher the system score, the more important it is to the solution of the Army's BDP deficiencies.

Workpackage scores are computed in a similar fashion, building on the computed system scores. Each workpackage is rated as to its significance to the fielding of a system. The AMC materiel developer assigns this criticality factor, a number 1 through 5, with the limitation that a workpackage can be rated a 1 (most critical) against only one system. The weightings associated with each factor are as follows:

<u>Factor</u>	<u>Weight</u>
1	10 points
2	5
3	2.5
4	1.25
5	0

The workpackage score is computed as the product of the system score times the criticality weighting, summed over all systems it supports:

$$\text{Workpackage Score} = \sum \text{Criticality Weight} \times \text{System Score}$$

The higher the workpackage score, the more important it is to the development of systems which solve BDP deficiencies.

### 3.3.2 Criticism of the Existing Prioritization System

The above technique for rank ordering systems and workpackages has received a lot of valid criticism. In general terms, this criticism focuses on the following aspects:

(1) The BDP itself is insufficient. It has an inherently short range of view of Army needs and is thus inappropriate for application to all tech base activities. It focuses entirely on the tactical battlefield at Corps level and below, and thus entirely ignores the Army's significant activities in the theater communications zone, in the Continental United States, and in strategic defense. The deficiencies themselves are rank ordered in a quasi-political process which raises doubts as to the objective value of the ranking or its suitability for long term RDT&E planning.

(2) The computation technique is flawed. Some other scheme should be used to translate the deficiency numbers, contribution values, and criticality factors into a quantitative measure of the virtue of a system or workpackage. In particular, the existing technique gives too much value to systems which support multiple deficiencies and to workpackages which support multiple systems, with too small regard for the importance of that support.

(3) The assignment of contribution values and criticality factors is flawed. The control process for assigning these values and factors is too easily circumvented, and thus the system and workpackage scores can be easily manipulated to the detriment of competing programs.

(4) The resolution of this technique is inadequate. A prioritization scheme based on the BDP, because of its limited scope, is inherently unable to make fine distinctions between competing programs. It is only suitable for coarse comparisons of program value. A knowledgeable manager must review the results and apply his expert judgement to adjust the computed rank ordering. It is difficult to imagine any scheme based on reasonable and economically obtained data that will supplant this managerial function.

### 3.3.3 Potential for Enhancement

There are numerous improvement efforts which might be undertaken to address these criticisms. In particular, a revised computational technique might be proposed which uses the same input data, yet eliminates some of the bias of the method toward systems which support multiple deficiencies and workpackages which support multiple systems. Any revised technique would have to be demonstrated to TRADOC and be approved by them for use in the MAMP system.

Attempting to make the methodology more comprehensive is probably unworkable. The BRDEC experience with the "goal programming" method illustrates the actual difficulty in obtaining objective data for use in the method, and the (un)satisfying realization that after all the systematic analysis is performed, human managerial judgement cannot be dispensed with.

Instead, the role of the knowledgeable manager could be reinforced by having the MAMP system provide a ready source of data in a consistent format. This will not be an easy task, because no small amount of data can adequately represent the virtue or complexity of a program effort. The current BRDEC briefing presentation format for programs (FOE matrix, executability charts, milestone charts) is an appropriate method for illustrating and initiating the discussion of substantive matters. Specialized MAMP reports should be tailored to match these standard formats and to provide backup materials should more detailed discussions be required. The existing reports which illustrate the impact of key fiscal reprogramming actions can be enhanced and employed as a decision aid.

### 3.4 MAMP Relationship to the LRRDAP

The relationship of the MAMP to the DA Long Range Research Development and Acquisition Plan (LRRDAP) has not yet been formalized. But, the MAMP has been directed to proceed in the direction of supporting the LRRDAP process. Much of the recent innovative work in the MAMP has focused on developing and evaluating usable tools for this effort. This effort is not yet complete. The reports which have been developed need additional definition and refinement to ensure that they are responsive and accurate.

The responsibility for submitting materiel development input to the LRRDAP rest with TRADOC. In preparation of Program Development Increment Packages (PDIPs), TRADOC consults with AMC to establish the RDT&E schedule and resource requirements for the materiel development initiative. The process of preparing requirements documents independently and continuously parallels this effort to ensure that the materiel development programs are responsive to Army needs. In what has been an annual submission to DA, TRADOC develops new PDIPs, revises existing PDIPs if necessary, and establishes its recommendation for the relative priorities for these PDIPs.

DA considers all PDIPs submitted, along with its funding guidance from DoD, and applies its own judgement in the rank ordering of the PDIPs. These are published as the DA LRRDAP. Based on the rank order, a particular PDIP is placed in a funding category (e.g., 'at risk', 'unfunded', 'high priority') to describe its likelihood of actually being funded. The whole of this process is well beyond the limited scope of this report. It is extremely complex, with many external factors that can significantly alter the PDIP structures and priority recommendations submitted by TRADOC.

The key fact is that the MAMP can contribute substantially to the development of PDIPs by providing the detailed information concerning RDT&E programs. As an AMC planning document, the MAMP shows the program schedules and resource requirements as AMC sees them. It forces close AMC coordination with the TRADOC representatives who are charged with preparing the PDIPs. Since it uses the TRADOC prioritization algorithms to rank order the RDT&E efforts, it can be used to predict in advance the relative ranking that TRADOC will assign. In a series of new specialized reports, the MAMP data can be presented in PDIP format, thus relieving the TRADOC action officers of much of the collation and assembly work entailed in preparing the PDIPs.

Other MAMP current reports also depict the consequences of DA PDIP priority decisions. By comparing the DA priorities with the results obtained using the TRADOC algorithm, inconsistencies in the DA funded RDT&E program can be easily spotted. These inconsistencies could be visible in non-executable development programs, or in insufficient funding for programs that address high priority Army needs. The appropriate Mission Area Manager or Commander can use this knowledge to assist him in making reprogramming recommendations, and to visualize the consequences of reprogramming actions.

## Section 4

### CONCLUSIONS AND RECOMMENDATIONS

#### 4.1 Conclusions

(1) The usefulness of the current MAMP database to the needs of BRDEC is somewhat limited. The database does not currently contain a complete and accurate list of the systems, projects, workpackages, and deficiencies of interest to the command. A preliminary list has been compiled but not validated. "Belvoir control files" need to be maintained, just as are the three mission area control files. This maintenance is not automatic, but requires careful attention and managerial judgement. Without these control files, BRDEC will get relatively little out of the MAMP system in the way of validated and comprehensive reports.

(2) Rigorous procedures need to be instituted across all MAMP sites to ensure that only good data is retained within the system. The actions of AMC in adopting BRDEC's recommendation concerning this issue is laudable, and initial procedures were established promptly. This is indicative of the rapid advance in the level of sophistication and detail of the AMC MAMP software.

(3) Better hands-on operator training in the use of the AMC MAMP software is required before that software will be widely accepted. The existing documentation is inadequate, and since the system software is changing so fast the documentation is unlikely to catch up any time soon. The training should also stress the ability of the MAMP sites to develop their own unique reports to support their unique requirements.

(4) The data contained in the MAMP database requires a lot of work to assemble and maintain. The quality control functions require a significant degree of knowledgeable high level attention. The MAMP system does not invent the data. Instead, human beings type the data into one of the many computers in the system. As a result, the data in the database may not always be correct but it does accurately reflect what was entered into it.

(5) The entire MAMP system (database and reports) structure needs to be rethought from the perspective of the final objectives. The MAMP objectives are to support the development of a LRRDAP responsive to the stated needs of the Army and to rationally allocate available resources to high priority programs. To this end, the PDIP related database structure needs to be stronger, to include PDIP control files, so that tighter fiscal accountability within mission areas can be maintained.

(6) The MAMP prioritization methodology might require additional attention. It is uncertain whether a more detailed and comprehensive methodology would yield any better results. The goal programming model provides a nice contrast to the MAMP technique, and proves that intricate approaches to prioritization have many drawbacks. No matter what technique is employed, AMC decision makers will retain their prerogative to override any computer algorithm to ensure that critical Army programs are continued. Although there are some fundamentally different prioritization schemes that

might be considered more "fair", it is TRADOC's decision as to which methodology to use in the MAMP. BRDEC can explore and recommend alternatives as it sees fit.

(7) The greatest potential for the MAMP is the close cooperation it engenders between the AMC materiel developer and the TRADOC combat developer in establishing goals and recommending programs to DA. In many cases, there has been insufficient communication between these parties. The MAMP provides a formal mechanism and a visible product of that communication which is less demanding than the preparation of requirements documents. As a planning tool, the MAMP excels in visualizing program structure and resource requirements for the future.

(8) The MAMP can also be used to augment the decision making process for allocating and reprogramming committed RDT&E resources. It can recommend actions that are responsive to the BDP, and it can illustrate the consequences of decisions in terms of program executability and fiscal balance.

#### 4.2 Recommendations

(1) BRDEC should establish a specific responsibility for ensuring that the BRDEC interests in the MAMP database are appropriately represented. This should include the specification and maintenance of "Belvoir Control Files" and supervisory quality control functions for BRDEC data.

(2) BRDEC should continue to present recommendations for new reports and procedures to be instituted into the AMC MAMP. AMC has shown a willingness to receive such recommendations and to act upon them. In every case they have extended and improved upon the original recommendation. This should include structural changes to the database to make the system more responsive to the PDIP submission process.

(3) Quality control functions for the MAMP database should be dispersed as much as possible. The directorate/program manager providing the data should be reviewing its own submissions. This may be accomplished by using data entry forms and screens, published examples and standards for quality data, and automated quality control audits. The distribution of MAMP data to the originators for use on personal computers should also be explored as a means to have the data scrubbed.

(4) The specification of a 'fair' prioritization algorithm should be left to TRADOC. The MAMP should be able to employ TRADOC internal procedures for establishing program priority. Extensions or deviations from this algorithm which are responsive to the resource allocation decision within AMC should be pursued and used independently.

## APPENDIX A

### MAMP DATABASE STRUCTURE

This Appendix describes the file structure of the MAMP database. Files are categorized as either "temporary" or "permanent". Permanent files contain original data, while temporary files are periodically rebuilt from the permanent data to assist in the running of the ACE reports. The files have been further classified according to their function:

<u>Permanent:</u>	Data Type Files
	Control Files
	Primary Data Files
	RDA Database Derived Files
	CSS/EMW/SOF MAMP Specific Files
<u>Temporary:</u>	RDA Funding Rollup Files
	Periodically Updated Files
	ACE Report Preprocessing Files

## A.1 Permanent Data Files

### A.1.1 Data Type Files

These files contain coded information regarding major data categories of interest to the MAMP system. They should not be modified by an individual MAMP site, since it is critical that the codes all represent the same data meanings throughout the MAMP system. The "acq" file defines what the acquisition code numbers mean (e.g., base case, type classified, development, etc.). The "ctl" file defines what the control code numbers mean (e.g., TRADOC Mission Area, DA Mission Area, MSC, or Flag).

```
file acq                                     permission all

field acq_code                             type integer
field acq_type                             type char 30
field acq_stt                             type char 4

data record length      36
number of records      13
number of indexes      1
acq_code               duplicates not allowed
```

```
file ctl                                     permission all

field ctl_code                             type integer
field ctl_type                             type char 20
field ctl_idx                             type composite
      ctl_code, ctl_type

data record length      22
number of records      5
number of indexes      3
ctl_code               duplicates not allowed
ctl_type               duplicates not allowed
ctl_idx               duplicates not allowed
```

### A.1.2 Control Files

The control files indicate which data is pertinent to each mission area or command. The control files are used to sift the large MAMP database and extract only that data desired for any particular report. Control files currently exist for deficiencies, projects, systems, and workpackages. Each control file has a similar structure, with a code and name field, to allow a specific item to be controlled in more than one mission area or by more than one command.

```
file defctl                                permission all

field dcl_code                             type integer
field dcl_name                             type char 12
field dcl_def                              type integer
field dcl_idx                             type composite
      dcl_code, dcl_name, dcl_def

data record length      16
number of records      189
number of indexes       3
dcl_code                duplicates allowed
dcl_def                 duplicates allowed
dcl_idx                 duplicates not allowed
```

```
file prjctl                                permission all

field pcl_code                             type integer
field pcl_name                             type char 12
field pcl_cmd                              type char 12
field pcl_cat                              type char 3
field pcl_subcat                           type char 4
field pcl_pe                               type char 5
field pcl_proj                             type char 4
field pcl_idx                             type composite
      pcl_cmd, pcl_cat, pcl_subcat, pcl_pe, pcl_proj

data record length      46
number of records      209

### A.1.3 Primary Data Files

These files contain the major MAMP user entered data. They generally define the deficiencies and systems in the database, while workpackage related data is generally derived automatically from the RDA database. The MAMP user should confine his data entry to these files (as well as the control files) as much as possible.

```
file assn                                     permission all

field assn_ssn                               type char 6
field assn_assoc_ssn                         type char 6
field assn_idx                               type composite
      assn_ssn, assn_assoc_ssn
```

#### A.1.4 RDA Database Derived Files

These files are loaded into the MAMP database from the RDA database. This transfer is accomplished periodically by AMC. This implies that the workpackage funding data in the MAMP will always be less than fully current. These files constitute a majority of the bulk of the MAMP database.

```
file actual                                permission all

field act_cmd                             type char 12

#### A.1.5 CSS/EMW/SOF MAMP Specific Files

These permanent files have been created at BRDEC to specifically support the submissions of the CSS/EMW/SOF MAMPs. They are not present at other MAMP sites. In the case of the "com" and "lrrdppri" files, the data contained in them may be absorbed into the AMC system (in which case the data will need to be transferred and the ACE reports revised). The other files deal with the shifting of deficiency numbers from BDP 85 to BDP 86, and the effect of potential realignment of LRRDAP priorities in POM 89. They will quickly become outdated.

```
file com                                     permission all

field com_com_line                          type char 10
field com_acq_strat                        type char 600
```

```
data record length      614
number of records       15
number of indexes        1
com_com_line            duplicates allowed
```

```
file defx                                     permission all

field defx_85                          type integer
field defx_86                          type integer
field defx_idx                         type composite

```

## A.2 Temporary Data Files

### A.2.1 RDA Funding Rollup Files

These files roll up the funding data from the RDA database into consolidated files for easier access by ACE programs. The funding data is normally presented in the RDA and MAMP systems as individual records for each workpackage and year. Thus a workpackage may have as many as eight records to describe its funding stream. When an ACE report conducts a joining operation on that workpackage, for example taking the workpackage description and joining it with its funding data, the ACE system creates a copy of the description for each of the eight funding years. This gets particularly wasteful when performing more complex joins of deficiencies to systems to workpackages to funding years. And naturally, the ACE system bogs down in managing the thousands of copies of duplicate data fields.

These files translate the individual funding records into a single consolidated record for each workpackage with all eight years represented. The flagr file allows for six flags for each workpackage. The shells "wkpfrroll" and "flagroll" automatically build these files.

```
file wkpfr                                permission all

field wkpfr_cmd                           type char 12
field wkpfr_cat                           type char 3
field wkpfr_wkpkg                         type char 7
field wkpfr_baseyr                       type integer
field wkpfr_g0                           type long

### A.2.2 Periodically Updated Temporary Files

These temporary files need to be updated frequently to ensure that the latest changes in the primary and control permanent files are reflected in the MAMP reports. The shell "priority" automatically updates these files. It takes approximately 45 minutes to run.

file asrr permission all

### A.2.3 ACE Report Processing Files

These temporary files are used in the creation of the more complex ACE reports. They contain intermediate data that is used in the preparation of specific reports and is otherwise meaningless. The file fundpro has the deficiency, commodity, or system funding data (separated by year, tech base or development category, and funded/unfunded quantities). The file idxpg contains the page numbers for each ssn discovered in the "sysdollars.out" file by the C program "readidx".

file fundpro permission all

APPENDIX B

MISCELLANEOUS PROCEDURES

### B.1 Shell Programs for Temporary File Reconstitution

The shell programs "priority", "wkpfroll", and "flagroll" automatically update the temporary files with the current MAMP system data. "Wkpfroll" and "flagroll" only need to be executed once for each update of the RDA derived permanent files, specifically the workpackage funding data file and the flag data file. "Priority" should be run more frequently, after major changes to the permanent files and before running production MAMP reports.

"Priority" updates seven of the temporary files. It received its name because at first it only created the system and workpackage BDP rating files (prior1 and prior2). Since then, it has been expanded to include the unique controlled ssN file (unissn), the highest priority PDIP file (hipri), the system to deficiency linkage rollup file (ssndroll), the associated ssN rollup file (assr), and the unique workpackage to system linkage file (uniwkp). "Priority" is a convenient and easy way to ensure that the temporary files have been rebuilt and do reflect the current data in the MAMP system.

## B.2 Shell Programs for Complex Report Execution

Several of the MAMP reports are multi-stage reports because of their inherent complexity and the limitations of the ACE programming system to accept the very large intermediate files they might create as single-stage reports. The multi-stage report first executes a subordinate ACE report, generating some intermediate values of interest. Then, these values are automatically read into a temporary file which is used by a second ACE report. This second report produces the final output that becomes the printed document.

The Deficiency Summary (defroll), Deficiency Funding Profile (defpro), and the Commodity Funding Profile (compro) are the three reports with this complex multi-stage execution. The shells defroll, defpro, and defroll, in the "../shell" directory, are used to execute these reports. Each of them creates a temporary data set which is loaded into the file "fundpro", and then the main ACE report is run. The calling sequence for these shells is:

```
expr [first pg#] | ../shell/defroll [pg letter] [code] [name]

expr [first pg#] | ../shell/defpro [pg letter] [code] [name]

expr [first pg#] | ../shell/compro [pg letter] [code] [name] [commodity]
```

The explanation for these calling sequences is contained in the introduction to Appendix C.

### B.3 Shell Programs for MAMP Production

Shell programs are also used for the rapid and convenient execution of the MAMP production runs. During the MAMP production period, many reports are prepared. Usually this tedious sequence of reports for one mission area is the same for all mission areas. Attention must be paid to the report's page numberings since they might depend on the length of previous reports. In addition, sometimes the execution of the many reports takes a long time and must be performed overnight. The shells described in this paragraph take away the drudgery of producing the MAMP reports by automatically stepping through the correct sequence of operating system calls needed to prepare the MAMP.

The following shell programs, found in the "../shell" directory, illustrate the use of shells to produce the MAMP. These are tailored for each mission area, and can be expected to change with each MAMP production run as the specific reports desired will change.

"Deficiency.css" produces the deficiency volume of the CSS MAMP. It creates the Deficiency Index, the Commodity Index, the Project Index, the Deficiency Summary, the Commodity Summary, the Project Summary, the PDIP to System Cross Reference, the BDP System Rankings, the BDP Workpackage Rankings, the LRRDAP Development System Priorities, the LRRDAP Workpackage Priorities, and the LRRDAP Procurement System Priorities. Each report is correctly paginated and controlled for printing. At the conclusion of the shell, the reports are moved to the "../output/cssreports" directory for storage. To verify the performance of the ACE reports, the file "defic.log" is available in the "../db" directory, which provides the ACE report output.

The simpler "system.css" and "wkpkg.css" similarly produce the system and workpackage volumes of the CSS MAMP. Again the reports are placed in the "../output/cssreports" directory, and the log files are created to verify the performance of the reports.

```

#### B.4 Shell Programs for Mass Actions to the Data Files

Occasionally, the user will need to make some mass changes to the database. These changes typically revolve around the deletion of an NSI or the change of an NSI to an SSN. Because the SSN is present in many different files, it can be extremely tedious to make all these changes and it is quite likely that one or more of the changes will not be made.

The shell programs presented below are used to rapidly change data records from one SSN to another, to delete all records with a particular SSN, or to print all data pertinent to a particular SSN. The correct calling sequence for these programs, found in the "../shell" directory, is:

```
updatessn [old ssn] [new ssn]
```

```
deletessn [ssn]
```

```
printssn [ssn]
```

Note that updatessn may have trouble in replacing the old ssn with the new ssn if corresponding records already exist for the new ssn. Then, the duplicate index value might cause Informix to not perform that update completely. The user might want to execute printssn for the new ssn first to see what data might already be present for the new ssn.

print uniwpk where uniwpk_ssn = "%{1}";
print idxpg where idxpg_ssn = "%{1}";
```

bye  
%  
echo "system data is at sysdata.out"

## B.5 Utility Programs

The following programs, written in the C language, are useful in managing the correct pagination of the MAMP volumes. Examples of the usage of these programs can be seen in the MAMP production shells described in B.3 above.

(1) `Pageread.c` (compiled to "pnext")

This program gets a number from input, increments it, and writes it to output. It is used to identify the correct first page number for a printed report. Its usage would be:

```
tail -10c oldreport.out | pnext | acego newreport
```

(2) `Pageodd.c` (compiled to "podd")

This program is similar to pnext, except that it finds the next odd number after the one input and writes that to output. This would be the correct page number if the new report must begin on a facing (odd) page. Its usage would be:

```
tail -10c oldreport.out | podd | acego newreport
```

(3) `Readidx.c` (compiled to "pidx")

This program reads the ssn and page data off of the file "sysdollars.out" (which must be directed to input), inserts the proper delimiter characters, and writes the pagination data to output. The resulting data is loaded into the temporary database file "idxpg" for use in the two System Index Reports. This saves hours of manual work in searching for the data and entry into the indexes. A sample of the proper usage for this program is found in the shell "system.css", but is reproduced below:

```
pidx < sysdollars.out > pidx.out
informer mamp <<%
delete noprompt idxpg;
bye
%
dbstatus mamp <<%
load ascii idxpg from "pidx.out"
bye
%
```

Jun 13 13:12 1986 pageread.c Page 1

```
main()
{
    int i;
    scanf ("%d",&i);
    printf ("%d\n",i+1);
}
```

Jun 13 13:12 1986 pageodd.c Page 1

```
main()
{
    int i;
    scanf ("%d",&i);
    if (++i%2 == 0) i++;
    printf ("%d\n",i);
}
```

Jun 13 10:37 1986 readidx.c Page 1

```
# include <stdio.h>
main()
{
    char junk1;
    char junk2[28];
    char ssn[8];
    int i,j,page;

    j = 1;
    while (j != 0)
    {
        for (i = 1; i <= 6; i++)
        {
            while ((junk1 = getchar()) != '\n' && junk1 != EOF);
            if (junk1 == EOF) j = 0;
        }
        if (j == 1)
        {
            scanf ("%s %s", junk2, ssn);
            for (i = 1; i <= 56; i++)
            {
                while ((junk1 = getchar()) != '\n' && junk1 != EOF);
                if (junk1 == EOF) j = 0;
            }
            if (j == 1)
            {
                for (i = 1; i <= 61; i++) junk1 = getchar();
                scanf ("%d",&page);
                printf ("%s:%d:\n", ssn, page);
                for (i = 1; i <= 4; i++)
                {
                    while ((junk1 = getchar()) != '\n' && junk1 != EOF);
                    if (junk1 == EOF) j = 0;
                }
            }
        }
    }
}
```

#### B.6 Perform Screens

Two simple perform screens have been developed to assist data entry personnel in reviewing and updating the permanent MAMP data files. These perform screens are located in the "../db" directory and may be executed by using: "perform system", or "perform wkpsys" from that directory.

These screens are not as thorough or as comprehensive as the AMC provided ones. Instead, they provide only the minimum essential capability to locate, enter, and update the data present on the System Summary Report which has been used as the major format for quality control and data entry.

APPENDIX C

SAMPLE OUTPUTS OF  
CURRENTLY AVAILABLE MAMP REPORTS

The CSS/EMW/SOF MAMP system consists of over 50 ACE programs, most of which produce printed and formatted output. This appendix presents sample outputs of each report, along with a brief description of the report content and the correct method for initiating the running of the report.

The parameters used in each report are described on the following table. The user would substitute appropriate data for these parameters, to cause the program to produce the correct output. Reports which require the running of more than one ACE program are separately described in Appendix B, paragraph 2.

A standard procedure has been followed in the use of parameters in these reports. The first parameter is always the starting page number. It is provided as the UNIX standard input to the ACE program by piping it from the standard UNIX function 'expr'. It can also be provided by piping the output from the special C programs 'podd' or 'pnext' (see Appendix B, paragraph 5), or if the program is not run in the background then the user can type the number in directly from the keyboard when he is prompted for the starting page number.

The formal parameters for the ACE reports always begin with the sequence '[pg letter] [code] [name]'. The page letter to be used is substituted for the parameter '[pg letter]'. It allows the user to easily specify the page lettering to use (or to omit with a 'Z') that is consistent with the position of this particular report in the MAMP document that is being prepared. The parameters '[code]' and '[name]' are the control file filters that are applied in keeping with the AMC database structure. These would be used to select the MAMP report for data relevant to the CSS or EMW or SOF or BELVOIR mission areas.

The remaining parameters are included to add control and flexibility for each individual report. In most cases they allow the ACE report to be tailored from a lengthy report for the entire mission area to a much smaller report that specifically addresses the data of interest.

EXPLANATIONS OF PARAMETERS USED IN THE ACE REPORTS:

[first pg#] an integer that describes the first page number to be printed on the report. Expr puts the page number into standard input so the report can be run in the background. In the foreground the user will be prompted to enter the page number from the terminal. See also the podd and pnext C programs.

[pg letter] a single character that states the desired page letter to be printed along with the page number. A "Z" will cause the report to omit the page letter altogether.

[code] an integer that references the code field in the mamp control files.  
1 = TRADOC Mission Area  
2 = DA Mission Area  
3 = MSC  
4 = Flag

[command] a character string of the command name or "\*" to indicate all commands.

[name] a character string that designates the specific name entry for the code that is entered in the mamp control files.

[class] a single character "U" or "C" that switches some reports between an unclassified and a confidential format.

[base yr] an integer that indicates which year is designated by year 0 in the workpackage funding data.

[ssn] a character string that designates a specific ssn or nsi to search on, or "\*" to indicate all ssn's.

[commodity] a character string of the commodity name, or "\*" to indicate all commodity names. Use " " to contain commodity names with a space.

[pro] a single character "Y" or "N" that switches the deficiency and commodity index reports between single column or double column entries for page numbers. Used if generating profiles.

[proj] a character string that designates a specific RDTE project or an "\*" to indicate all projects.

[pdip] a character string to designate a specific pdip/increment or an "\*" to indicate all pdips.

basetc

This report produces a streamlined summary of type classified systems. It used to also show base case systems, and can be reinstituted quickly.

expr [first pg#] ! acego ../neil/basetc [pg letter] [code] [name] [command]

mamppdip

This report produces a confidential listing of the pdips, priorities, systems, and workpackages appropriate to a single mission area. It is our first attempt to recreate the lrrdap out of the mamp database.

expr [first pg#] : acego ../neil/mamppdip [pg letter] [code] [name]

C-51

pdipcom

This unclassified report summarizes the systems in a mission area by the commodity line that they belong to. It is like the commodity summary, but it is intended to be used to help structure future pdip submissions

expr [first pg#] : acego ../neil/pdipcom [pg letter] [code] [name] [class]

# AIR DROP PDIP COMMODITY SUMMARY FOR CSS

Acquisition Strategy THIS LINE CONTAINS SYSTEMS FOR AIRDROP OF PERSONNEL (MASS ASSAULT AND SOF), WEAPONS SYSTEMS AND HEAVY EQUIPMENT/VEHICLES AND SUPPLIES (FOOD, AMMO, FUEL) DEEP BEHIND ENEMY LINES WHERE CONVENTIONAL MEANS OF DELIVERY/RE-SUPPLY ARE IMPOSSIBLE TO EMPLOY. DEVELOPMENTAL SYSTEMS WILL ALLOW AIRDROP TO BE CONDUCTED AT MUCH LOWER ALTITUDES (1200 TO 300 FT) THEREBY REDUCING AIRCRAFT VULNERABILITY, INCREASED PAYLOAD UP TO 60,000 LBS (AS COMPARED TO 35,000 LBS AT PRESENT), REDUCED RIGGING TIME AND LABOR AND ELIMINATOR OF PAPER HOMEYCOMB THRU SOFT LANDING SYSTEMS AND DIVE-DN/DIVE-OFF CAPABILITY, REDUCED

#### wkpsys

This diagnostic report shows the linkages between workpackages and systems, sorted by workpackage, and shows which systems are in the control file, the pdip's that the systems are in, the system pdip and bdp priorities, and the unique ssn-pdip combination that the workpackage is linked to for fiscal accountability.

expr [first pg#] : acego ../neil/wkpsys [pg letter] [code] [name] [proj]

Jul 25 12:16 1986 defroll Page 1

(Deficiency Summary

Last changed 2/4/86. added report mission area, system tradoc mission area,  
and date-time stamp.  
2/7/86. added page letter parameter. moved page number to input. changes to  
ssndesc .  
3/20/86. changed to mamp database.  
3/29/86. changed to include all systems.  
6/10/86 revised the read statements.  
6/13/86 added def\_class for classification. corrected printing of cont\_value.  
7/23/86 changed the workpackage input variables to generic years.  
7/25/86. changed to generic rdte rollup file fundpro (from syspro1). }

( POM 89 REPORT OF PDIPS WITH CUMULATIVE RDTE FUNDING SHOWN.

6/23/86. taken from laura's pdipwkp report. This differs in that it works  
with the projected pom89 pdip alignments and priorities.  
6/24/86. changed pom 89 pdip structure. added pdip parameter.  
7/10/86. changed the pom89ssn file structure.  
7/15/86. changed uniwkp\_wc to uniwkp\_srf. }

{ last modified 2/6/86 to add mission area parameter and date-time stamp.  
2/7/86. added page letter parameter.  
Also modified 2/26/86 for Exec. Assmt.  
revised 3/3/86 to remove belvoir specifics and to replace peproj in the mamp.  
Modified 5/21/86. changed to mamp database.  
5/27/86 cleaned up a bit. Added cumulative project funding variables.  
6/2/86 removed mandatory check for being in the system control file.  
now only reports if in the mission area control file.  
6/4/86 added workpackage criticality factor. Sort output by beginning year.  
6/6/86 added one extra space for the wpk number. removed one space from  
title.  
7/23/86 changed wkpsys\_srf to wkpsys\_srf in keeping with iitri's usage. }

Jul 29 12:54 1986 sysdollars Page 1

(System Summary with Dollar Values inserted.

Last modified on 2/4/86 to add date-time stamp, tradoc ma,  
ma parameter, and workpackage rating factor.  
2/7/86 to change commodity and mission area designators.  
5/12/86 changed to the mamp database. changed the logic so that all systems  
with any workpackages and all developmental systems - regardless of  
workpackages - will print. Added page letter parameter.  
5/13/86 removed \*1000 in lrrdp funded amounts. It's already in \$1000s.  
5/16/86 added report group parameter (t)  
5/21/86 changed parameter t to "matches" condition.  
6/9/86 removed group parameter (t), this report will print all systems  
including type classified. Removed < completed >.  
6/13/86 changed classification to include the possibility of a secret  
system description. Get classification from ssn\_class.  
7/3/86 corrected project linkage to allow workpackages in control file  
linked to other mission areas.  
7/10/86 changed wkpsys\_wc to wkpsys\_srf in keeping with iitri's usage.  
7/15/86 extensive modifications to print multiple pdips. }

< SYSTEM RTE FUNDING ROLLUP PRODUCER. This program is the precursor to defroll. It summarizes the rte funding for a system. It does not include 6.5 funding for a system. >

< 5/19/86. changed to the mamp database.

5/20/86. made corrections.

6/10/86. removed the code and name parameters. This program now works for all systems in the wkpsys file and should be updated occasionally from the shell syspro1.

7/23/86. changed from year to generic data for the fields.

7/25/86. changed to the file structure of fundpro.  
reinststituted the code and name parameters.>

( System Resource Report with RDTE Funding Chart.

Modified on 2/5/86 to include mission area parameter and date-time stamp on each page.

Modified on 5/19/86 to add command and group parameters.

and to change report in order to run in mamp.

Made corrections. 5/20/86

5/29/86 merged into a single file for all commands as an option.

6/10/86 removed the group parameter. }
